Understanding Global Development

Wealth, Health & Access across 237 countries

Mini-Project 3 | Advanced Tableau Storytelling & Interactive Analytics

ECONOMY | DEMOGRAPHICS | PUBLIC HEALTH

How do wealth, health and access fit together?

A research organization needs interactive dashboards to analyze economic, demographic and public health indicators.

ECONOMY

- GDP and GDP per capita
- Real growth rate
- Inflation and unemployment
- Public debt, exports, imports

DEMOGRAPHICS

- Population and area
- Birth and death rates
- Total fertility rate
- Continent and income group

HEALTH & ACCESS

- Life expectancy
- Infant mortality
- HIV/AIDS prevalence
- Internet users

Three questions this story answers

1. Does wealth predict how long people live?
2. What breaks that pattern, and where?
3. Who is online, and who is being left behind?

Global Development Overview

Wealth, Health & Access: Does Income Explain Development

Income predicts longevity, but epidemics and digital access reveal the gaps. Select a continent to highlight it across all charts

Does Wealth Predict Longevity?

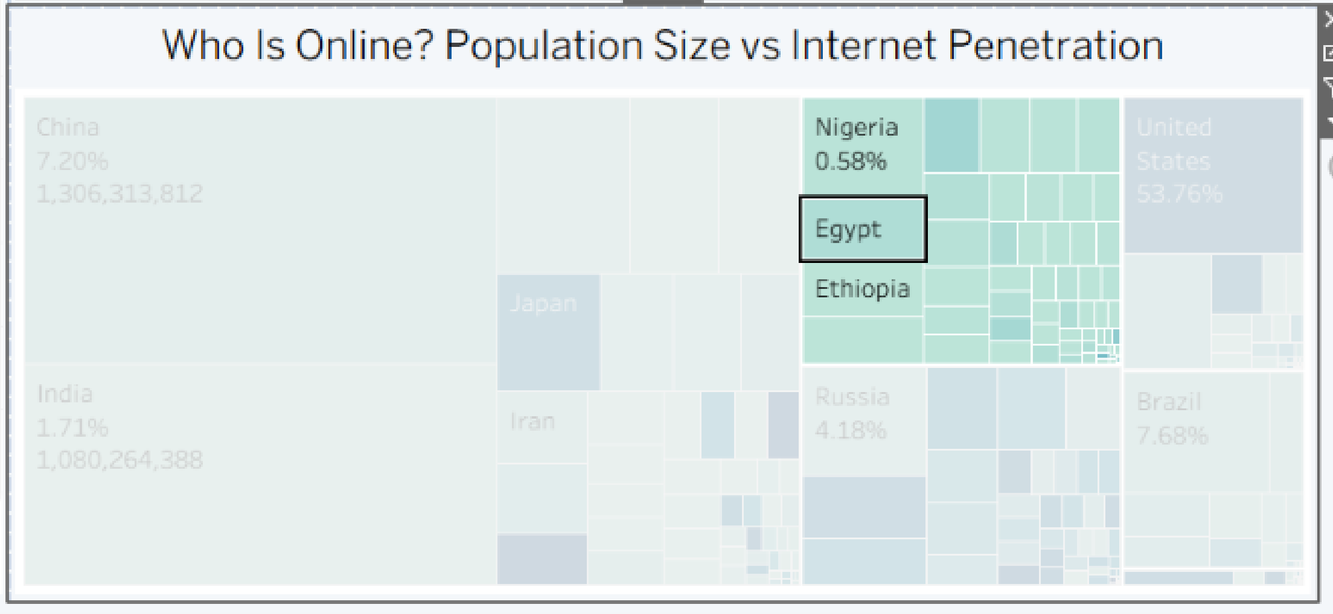

Average Life Expectancy: Continent × Income Group

Income Group	Africa	Asia	Europe	North America	Oceania	South America
1. Low	47.26	63.08			61.71	
2. Lower-Middle	51.12	64.44	69.96	69.74	68.20	69.07
3. Upper-Middle	60.36	71.50	71.54	72.68	69.79	73.10
4. High	72.38	77.30	78.30	76.09	77.21	76.02

Continent
- Africa
- Asia
- Europe
- North America
- Oceania
- South America

Who Is Online? Population Size vs Internet Penetration

pulation
7,012
500,000,000
1,000,000,000
1,306,313,812

What this means for the research organization

r = 0.73

Wealth tracks longevity

Across 224 countries, GDP per capita and life expectancy are strongly related (log scale).

So what: income is a useful signal for health planning, but not the whole story.

34–44 yrs

HIV breaks the pattern

Six southern African countries have middle incomes but life expectancy of 34–44 years (HIV 21–39%).

So what: target health programs by disease burden, not by income level alone.

~80%

The digital divide is huge

About 80% of people in countries with data live where fewer than 1 in 10 use the internet.

So what: digital inclusion should focus on Africa and Asia, where most people live.

Keep in mind

- Single snapshot with no year column: no change over time, and the figures look dated.
- 22 countries have no internet data, and 2 cannot be placed on the map.
- Correlation is not causation: income does not by itself explain health.
- Income groups use custom thresholds, not an official classification.

Appendix: how the data was prepared

For transparency: every cleaning step is documented in a Jupyter notebook with a cleaning log.

263 → 237

countries

Removed 1 aggregate (the EU) and 25 empty entities

45 → 39

columns

Dropped 7 sparse oil and gas columns, added a Continent column

16

names standardized

e.g. Burma → Myanmar, Korea North → North Korea

235 / 237

countries on the map

Netherlands Antilles and Johnston Atoll cannot be geocoded

1. Load file (sep ';', skip type row)
2. Remove aggregates and empty entities
3. Standardize country names
4. Add Continent column
5. Keep missing as Null (never fill with 0)

Two sparse columns were kept on purpose: public debt (108 countries) and oil reserves (96), as both are central to the analysis.

The file is a single snapshot with no year column, so "trend" means relationships across countries, not change over time.
